

On the presence of *Tetrao partium* (Kretzoi, 1962) (Aves: Tetraonidae) in the Late Pliocene of Bulgaria

Zlatozar BOEV

Geographical and stratigraphical distribution of *Tetrao partium* (Kretzoi, 1962)

The fossils of *T. partium* were reported from: Early Pleistocene - Bettia in NW Romania (final of the Early Pleistocene /Biharian/ (BRODKORB, 1964; JURCHAK & KESSLER, 1987); Voigtstedt in Germany (JANOSSY, 1965); Beremend 16 in S Hungary (ca. 1,0 Ma) (JANOSSY, 1992); Villany 3 („Lower Pleistocene“), Villany-Nagharsany-hegy („Lower-Middle Pleistocene“), Osztramos 2, 5, Somssich Hill 2 („Early Villafranchian“) in Hungary (JANOSSY, 1976; 1986); Middle Pleistocene - Stranska Skala in Slovakia (JANOSSY, 1972); Carpathian Basin (JANOSSY, 1980); Gombaszog, Pispokfurdo 1,2, Mehesz, Tarko, Varhegy-Budapest and Vertesszollos in Hungary, Seneze in France, and Tchorkow in Ukraine (JANOSSY, 1976; 1986).

JURCHAK and KESSLER (1987) summarized that the species was wide spread throughout Europe (Stranska Skala /Czechoslovakia/, Hundsheim /Germany/, Csarnota, Tarko /Hungary/, etc.). It is worth noting, that both species (*T. tetrix* and *T. partium*) coexisted in the Gunz-Mindel Interglacial in Romania (JURCHAK & KESSLER, 1988).

Thus, the geographical range of *T. partium* following JANOSSY (1976) encompasses a large territory of Europe from France to Ukraine, while stratigraphically the species was spread from the Middle Villafranchian to Mindel. At the same time, MLIKOVSKY (1996) lists no Tertiary sites of that species in Europe. Most abundant summary data were cited by TYRBERG (1998). According to him, the stratigraphic range of *T. partium* is between 19 and 21 MNQ zones, while the geographic range encompasses France, Hungary, Romania, Austria, Germany and former Czechoslovakia.

The finds of *Tetrao partim* from Bulgaria

The finds have been collected from the site near Varshets (43°13' N, 23°17' E), NW Bulgaria. This site represents a ponor in a rocky hill, 6 km NNE of the town of Varshets. They are kept in the Collections of the Fossil and Recent Birds Department of the National Museum of Natural History, Bulgarian Academy of Sciences - Sofia.

Horizon: Unconsolidated sediments accumulated in the filling of clay terra-rossa with unstratified inner structure. The fossil bones are broken, sometimes making a kind of bone breccia.

Chronostratigraphy: Middle Villafranchian. The associated mammalian fauna attributes the site to the MN 17 zone (SPASSOV, 1997; 1998; V. POPOV - pers. comm.).

Measurements: see Tables 1-10 and Fig. 2.

Collections acronyms: UCBL - Centre des Sciences de la Terre at the Université Claude Bernard - Lyon; NMNHS - Fossil and Recent Birds Department of the National Museum of Natural History, Bulgarian Academy of Sciences - Sofia,

Comparative material examined: The fossils from Varshets were compared with the homologous skeleton elements of the following species: *Tetrao tetrix* - NMNHS 1/1982; 2/1983; UCBL 131/4; *Tetrao urogallus* - NMNHS 2/1983, 4/1989, 5/1996; *Lagopus lagopus* - NMNHS 1/1986; *Lagopus mutus* - NMNHS 1/1986; *Tetrastes bonasia* NMNHS 1/1995; *Phasianus „obscurus“* - UCBL 458/1; *Phasianus versicolor* - UCBL (VI-73); *Syrmaticus reevesii* - UCBL 457/1; *Gallus gallus* - UCBL 456/1; UCBL 454/3; *Gallus sonnerati* - UCBL (II-73); UCBL 459/1; *Numida meleagris* - UCBL 453/2; *Alectoris chukar* - UCBL 126/6.

Comparison

All finds show clear appurtenance to Galliformes. Both, morphologically and dimensionally, the finds from Varshets belong to a Tetraonidae representative. Larger tetraonids as the recent *Tetrao urogallus* and *T. parvirostris*, and the fossil *T. praeurogallus* and *T. macropus* may be excluded from our considerations, because of the larger size of the first two and the chronological differences of the last two.

Coracoid: The Uppermost Pliocene *T. conjugens* is characterized by its larger size and close morphological resemblance to *T. tetrix* (JANOSSY, 1976). Janossy wrote in the same paper: „The cranial part of coracoideum ... appears to be slender ...“ (p. 20), which corresponds to the finds from Varshets. In any case, the finds from Varshets can not be referred to the capercaillie group. The bone sculpture of the articular parts and the bone size unequivocally suggest a species of the Black Grouse (*Lyrurus*) type. It was reported (KRETZOI, 1961; JURCHAK & KESSLER, 1987), that the dimensions of *Tetrao (Lyrurus) partium* are intermediate between these ones of the recent *T. tetrix* and *Lagopus lagopus*. The applied photograph of a distal (cranial) fragment of the left coracoid of *T. partium* from Voigtstedt (JANOSSY, 1965, Table VII, 19) fully corresponds to our finds of Varshets. In comparison to *T. tetrix*, N 278 and N 279 have a relatively shorter acrocoracoidal part (measurement „b“), while in comparison to *Lagopus lagopus* they have a wider impressio lig. acrocoracoidei. Compared with *T. tetrix*, the N 280 and N 281 finds have an almost twice smaller hook-like processus above the angulus medialis in the sternal part, while in comparison with *L. lagopus*, they have a twice wider facies articularis sternalis and more massive diaphyses.

Ulna: Compared with *L. lagopus* the N 282 find has a longer cotyla dorsalis, wider depressio m. brachialis and thicker diaphysis in the proximal end. The N 283 find has a much smaller condylus ventralis and a larger condylus dorsalis in

comparison with the same species. Dimensionally the find differs significantly from the *Tetrao* spp. of the *urogallus* lineage.

Femur: In comparison with *T. tetrix* the N 157 find has a smaller facies articulationis antitrochanterica, a larger surface of fovea ligamenti capiti and a less developed colum femori, while in comparison with *L. lagopus* and *L. mutus* it has a more robust appearance and a thicker colum femori. In comparison with *T. urogallus*, N 157 has a shallower fovea ligamenti capitis and longer colum femori.

Phalanx prox. dig. majoris dex., N 158: Its dimensions are larger than these of *L. lagopus* and *L. mutus* and smaller than these of *T. urogallus*. Morphologically it stands closer to g. *Tetrao* (*T. tetrix*), than to *Lagopus*.

Phalanx I dig. 2 pedis, NN 185, 194, 201 and phalanx II dig. 3 pedis, N 245: Dimensionally these finds with their smaller size differ significantly from the *Tetrao* spp. of the *urogallus* lineage. They are also larger than *Lagopus* species.

Conclusions

The finds of *Tetrao partium* from Bulgaria complete our data on both, the geographical and the stratigraphical distribution of that galliform. The remains from Varshets confirm its wider distribution throughout East Europe in the Middle Villafranchian. Thus, *T. partium* is known from France, Germany, Slovakia, Hungary, Ukraine and Bulgaria. These are some of the earliest evidences for the existence of that species as a whole. The Bulgarian finds are the first records of the species on the Balkans and mark the southern limit of its range.

Acknowledgments

I am very grateful to Dr. Cécile Mourer-Chauviré for the opportunity to work on these and other Bulgarian fossil materials of birds in the Centre de Sciences de la Terre of the Université Claude Bernard - Lyon 1. The study was sponsored by the Fondation Scientifique de Lyon et du Sud-Est (France) and the National Science Fund (Project No B-202/1992) (Bulgaria).

За наличето на *Tetrao partium* (Kretzoi, 1962) (Aves: Tetraonidae) в късния плиоцен в България

Златозар БОЕВ

(Резюме)

Чрез 15 находки от средно-вилафранкското находище (вилан) край гр. Вършец се доказва разпространението на вида в България и се допълва значително неговата морфологичната характеристика.

Направен е преглед на географското и хроностратиграфското разпространение на вида, обхващащ данни за 14 негови находища от среден вилафранк до миндел. Вършец е най-южното му и най-древно находище, с което се разширява значително ареалът на този фосилен тетраонид в края на плиоценена. Ареалът му е обхващал средновисоките планински райони във Франция, Германия, Словакия, Унгария, България и Украина. *Tetrao partium* не е бил предшественик на *T. tetrix*, а негов съвременник.

В материала са представени coracoid, ulna, femur prox., phalanx prox. dig. majoris, synsacrum, pars axialis, tarsometatarsus, phalanx I dig. 2 pedis и phalanx II dig. 3 pedis, някои от които като анатомични елементи досега бяха неизвестни за този вид.
