VIII. Description of the Cermatia longicornis and of three new Insects from Nepaul. By Major-General Thomas Hardwicke, F.R.S. and L.S. &c.

Read January 21, 1823.

Order. CHILOPODA.

Fam. CERMATIDÆ.

Genus. CERMATIA Illiger.

Scutigera. Lam., Latr.—Scolopendræ pars Linn., Fab.

CERMATIA LONGICORNIS.

TAB. V. Fig. 1.

Scolopendra longicornis. Fab. Ent. Syst. ii. 390.

Scutigera longicornis. Latr. Hist. Nat. des Crust. et Ins. vol. vii. p. 89.

Scutigera lineata? Latr. Dict. d'Hist. Nat. vol. xxx. p. 446.

Body, when viewed beneath, having sixteen segments, which are united above by eight unequal scuta. Antennæ of a pale colour, as long as the body, finely setaceous with three principal joints, each of which is numerously articulated. External maxillary feet or mandibles strong, subulate, incurvate, four-jointed. Maxillary palpus four-jointed, hairy, or rather spinulose, longer than the mandibles. Eyes large, hemispherical. Feet very long, fifteen on each side, with the last pair twice as long as the others. The principal

cipal articulations of the legs, viz. the two femoral joints and the tibiæ, are armed with stiff setæ. The tibiæ are flattened, angular, and of a pale colour, marked with transverse bands of a blueish-black. The tarsi are filiform, numerously articulated, and ending with a single subulate claw; and, with the exception of the hinder pair, which are transversely banded like the tibiæ, are of a pale-yellow colour.

The longest specimen hitherto examined was one inch and a quarter in length from the base of the antennæ to the tail. Antennæ one inch and a half; and posterior legs  $2\frac{2}{10}$  inches.

This insect is found in damp houses under floor mats in all parts of Bengal, Bahar, and Orissa, but mostly during the rainy season, as Illiger has observed of his *C. lineata*. When living, the colours of the back and legs are bright, and varied between yellow, black, and brown; and although the above description by no means corresponds with the *Cermatia livida* described by Dr. Leach in the third volume of the *Zool. Miscellany*, it appears to answer to that of the *Scolopendra longicornis* of Fabricius.

Order. NEUROPTERA.

Fam. PANORPIDÆ.

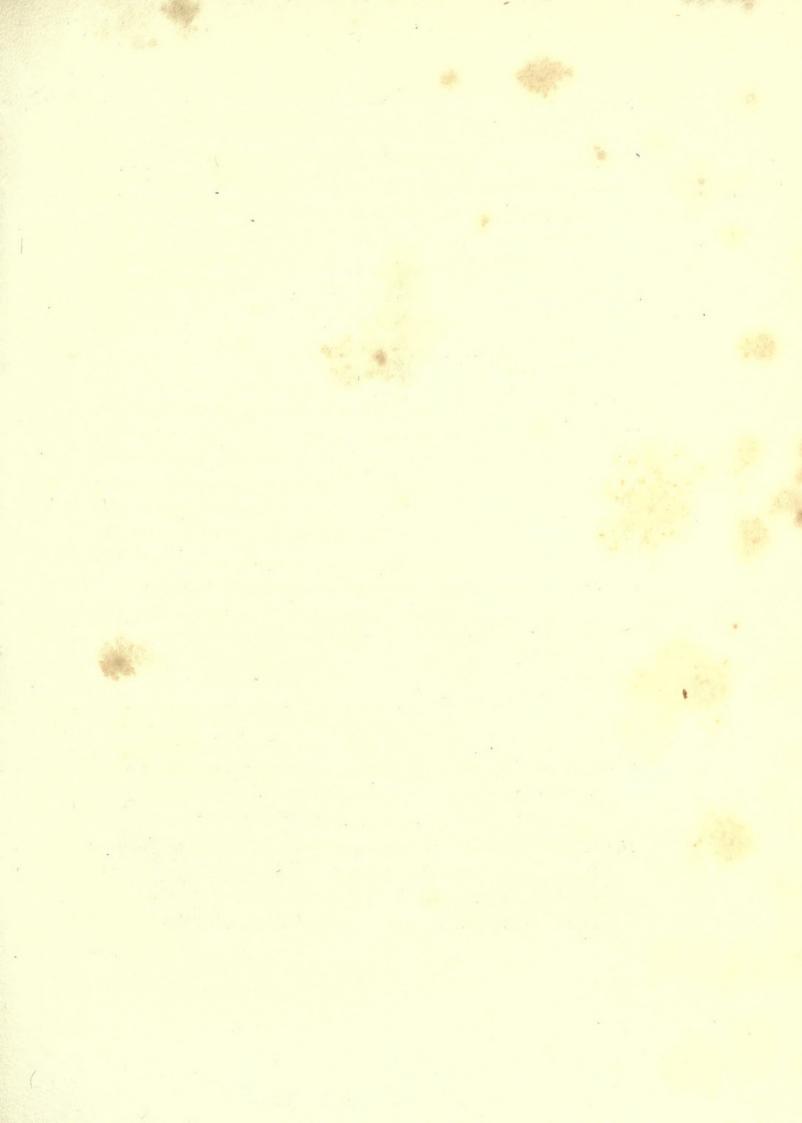

Genus. PANORPA. Linn.

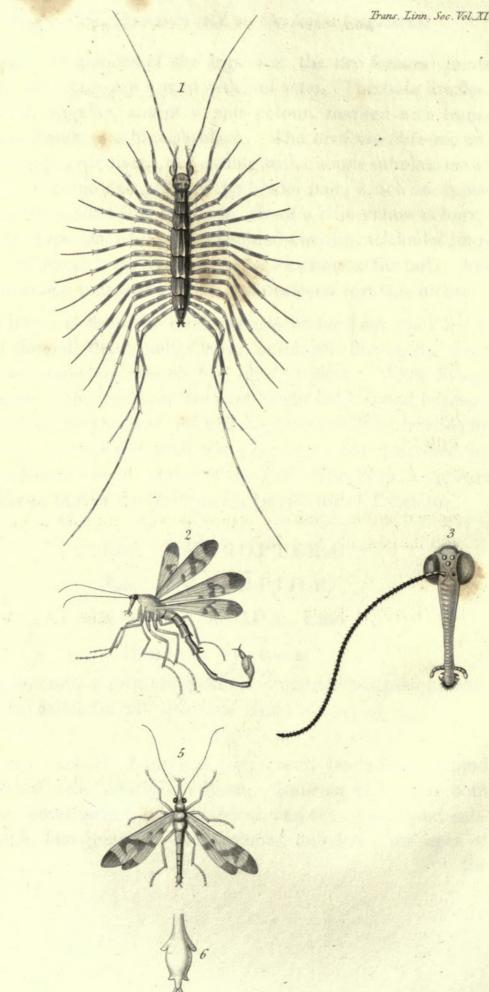

## PANORPA FURCATA.

P. rufa, antennis nigris, alis hyalinis: superioribus puncto marginali fascià furcatà apiceque nigris.

## ni staludus generas TAB. V. Fig. 2-6. Meines Interpret

Head small, vertical. Eyes large, prominent. Ocelli three, behind the antennæ, nearly confluent. Rostrum as long as both head and thorax; subcylindrical, smooth. Palpi four, subequal, four-jointed. Jaws minute, subulate; the apex of the

the rostrum ciliated. Antennæ filiform, as long as the body; articulations very numerous (about 52), placed between the eyes and approximating at the base. Body elongate, subcylindrical, slightly marginated, tapering: the dorsal margin of the third segment in the male, produced into an obtuse spur, equal to the breadth of the next segment; and the last segment being furnished laterally with two similar setæ. The tail of the male consists of three joints, the two first cylindrical and as long as the abdomen; each enlarged at its junction with the next; the third joint short, urnshaped and forcipated; the forceps resembles the sting of the Scorpion. Wings long, ovate, subequal; broadest at the apex, a little longer than the body, hyaline; nerves brown, spotted at the base, double-barred at the apex. Legs long, the posterior pair longest, the shanks armed behind with two straight setæ. Tarsi five-jointed, the first as long as all the rest: all finely armed with setaceous hairs. Claws black, finely pectinated; the surface of all the legs, when viewed under a lens of strong power, appears to be finely annulated.

# GERRIS LATICAUDATA.

G. rufa, antennis tarsisque nigris, caudâ utrinque bidentatâ supra unguiculatâ infra penicillatâ.

# TAB. VI. Fig. 1-4.

Antennæ filiform, four-jointed, the first elongate, all cylindrical, porrected, black; the last joint shortest and incurvate. Head shorter than the thorax; eyes prominent; snout inflected, short. Thorax roundish, convex, smooth; thicker and shorter than the abdomen. Body sublinear, of eight distinct rings and a dilated tail, pointed at the apex, and furnished on each side with a pencilled tuft and a hooked seta. Wings incumbent, cruciate, membranaceous, hyaline, subequal. Legs, the anterior pair simple, stronger than the rest, porrected; the tarsi two-jointed. The anterior thighs compressed, with the inferior margins densely hairy; the second pair twice as long as the first, and having their inferior margin ciliated; the third pair rather longer than the second, with the thighs cylindrical, armed, as in the Grasshopper tribe; the tarsi of the four posterior feet are apparently two-jointed, but so finely tapered as to require a strong lens to detect the articulation and the didactyle claws.

The prevailing colour of the insect is a light brown; the thighs of the first pair of legs longitudinally streaked with black; thorax and sides beneath whitish silvery down.

Length of the insect from the base of the snout to the end of the tail eleven lines.
