the darkest, and have a plain, curved claw at their extremity. The abdomen is short, oviform, hairy, convex above, and projects a little over the base of the cephalo-thorax; the upper part is of a sooty-brown colour; the anterior extremity, contiguous to the cephalo-thorax, the sides, under part, and spinners have a dull yellowish-white hue; the colour of the branchial opercula and tracheal stigmata is also dull yellowish-white, the former having a tinge of brown, and in the space between them there is an irregular whitish spot.

This spider, which had not arrived at maturity, was taken in

Pernambuco in 1858 by Mr. Eyton Williams.

XXXIII. - Description of two new species of Chalk Starfishes. By H. SEELEY, Esq.

To the Editors of the Annals and Magazine of Natural History.

GENTLEMEN, 45 Great Ormond Street, Sept. 3, 1858.

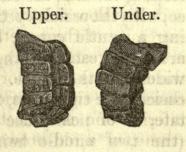

The fragmentary condition of the specimens described might seem to render the accuracy of the descriptions doubtful; but no one can doubt that the essential specific characters of a Goniaster are nearly as well exemplified in a single side as they would be in a whole Starfish, the only danger being that in specimens so imperfect you might have an abnormal form, a monstrosity, or a made-up fossil: but all these possibilities have been fully discussed, and the subjects of them submitted to an exceedingly careful examination, the result of which has been that the evidences of both specimens being new species have so increased, that it would be useless longer to delay their publication. Neither species is likely to be mistaken for any yet described.

> Truly yours, HENRY SEELEY, Hon. Sec. to the Museum, W.M.C.

Goniaster (Goniodiscus) Forbesii, S.

Body? Sides very gently curved outwards. It has two oblong, convex, rather swollen superior intermediate marginal

plates, each bearing two rows of laterallyoblong, proportionately large protuberances. The inner edge of the ossicles is slightly rabbeted; this appears to the naked eye as possibly caused by the two protuberances there placed being greatly developed; but a lens shows the margin as a flat field, out of which the cushioned

surface, bearing the hill-like prominences, rises. The superior oculars are greatly developed, and more swollen than the intermediate bones; they are one and a half times as large as the latter, and, in size and shape, look as though formed of an ordinary marginal and the half of another divided diagonally; they carry three rows of prominences, and have a rabbet on the inner edge similar to that on the others. The superior plates are steep and deep, compared with the inferior plates, over which they slightly project, so that when the under surface is seen, the margin appears step-like. The under-plates on a side were in all six in number, one being under each intermediate marginal, and two under each of the eye-plates; they are flat, smooth, and roundedoff at their outer edge. The margin of each inferior ossicle is bordered by a slight rabbet, the walls of which are connected by a number of partitions which give it the look of a line of little pits. The fragment consists of one complete side, wanting only a terminal inferior ocular plate. It measures in length 5ths of an inch.

This species is easily distinguished from every other by the number of its superior marginals. In size it comes nearest to rugatus, Forbes, which it is not unlike in the markings on its

dorsal marginal ossicles.

Chalk of Hertford.

Goniaster (Goniodiscus) Furnivalli, S.

Body pentagonal, with sides gently curved outwards. When

perfect, having on the dorsal surface, in each side, ten oblong, convex, rather finely-granulated marginal ossicles, all steep or abrupt, and deep. Of these the oculars are not preserved, but must have been small and triangular, and have projected slightly over the inferiors. Of the four intermediate marginals the two middle ones are slightly the shorter; this arises from the inner side of the intermediate marginals sloping towards the outer side, and so, with the ossicles between, forming a gentle curve; but all four are of the same width, and rather wider than the others. Theinferior ossicles are eight, flat, finely punctate, all of nearly the same width (the two middle being slightly

Under surface.

Upper surface.

the narrowest), broader than the superior, and slightly concave at the meeting of the two exposed sides. The inferior eye-plates are wedge-shaped. Ossicles of inferior (?) surface of disk punctate.

Length of a side 11 inch.

This species is well distinguished from every other unmargined form, except rectilineus, M'Coy, by its finely-granulated superior marginals; and from that, to which it approaches nearest, by the punctations on its inferior plates, and by its wedge-shaped inferior oculars. About the size of uncatus.

Chalk of Gravesend.

Both specimens are in the Collection of the London Working Men's College, Great Ormond Street.

XXXIV.—On a new genus of European Coleoptera. By T. Vernon Wollaston, M.A., F.L.S.

Fam. Melyridæ.

Genus Antidipnis.

Corpus minutum, ovatum, in utroque sexu (nisi fallor) apterum: capite antice angustato, clypeo brevi membranaceo; oculis prominentibus. Antennæ longe ante oculos insertæ, filiformes, distincte 11-articulatæ; articulo 1 mo reliquis longiore, paulo robustiore, leviter subclavato; 2do brevi; inde ad decimum longitudine subæqualibus; 11^{mo} ovato. Labrum transversum, antice truncatum, apicem versus membranaceum. Mandibulæ triangulares, corneæ, basi latæ, apice incurvæ acutæ, necnon (in una saltem) fissæ. Maxillæ bilobæ; lobis membranaceis, apice obtusis pubescentibus. Palpi maxillares in sexu masculo valde diversi quam in fæmineo: in maribus longissimi (fere articulum antennarum septimum attingentes), articulo 1^{mo} minuto, 2do huic paulo crassiore elongato, 3tio 4toque maximis valde incrassatis (illo ovato apice truncato, superne intra apicem externum eroso, hoc inæquali subquadrato, ad apicem ipsum spongioso); in faminis multo breviores (haud ultra articulum antennarum tertium extendentes), articulo 1mo minuto, 2do 3tioque huic paulo crassioribus (hoc illo vix breviore), 4to elongato (2di 3tiique conjunctim longitudine æquali), leviter crassiore, fusiformi. Palpi labiales in utroque sexu fusiformes; articulo 1mo parvo, 2do longiore crassiore, subclavato apice truncato, ultimo huic longitudine subæquali sed paulo tenuiore, fusiformi basi truncato. Ligula a me vix distincte observata. Pedes longiusculi, graciles, valde cursorii: tibiis ecalcaratis, posticis basi leviter subcurvatis: tarsis elongatis filiformibus, articulo 1mo longiusculo, anticis in sexu masculo 4-articulatis: unguiculis simplicibus. Ab αντί pro, et δείπνον cœna (sc. cœnæ loco).

The curious little beetle from which the above generic characters have been compiled was captured by myself, near Lisbon, on the 17th of last July, in stercore arido humano (a somewhat remarkable habitat for a Malachian, and one I suppose which it must
