

proaches nearer to *Nepenthes*, where the dehiscence of the operculum and of the pitcher is also horizontal or very nearly so. Only here the operculum continues, whilst elsewhere it is removed.

B. The *polyphyllous ascidia* are formed of several leaves. Up to the present time diphyllous alone have been observed, but the study of the conditions in which they arise evidently proves that there is great probability of our finding triphyllous, tetraphyllous, pentaphyllous, and in short polyphyllous, especially in plants where the leaves are verticillate.

It is thus that a just appreciation of things anticipates ultimate discoveries, and it is the best proof that a *science of observation* is quite as exact as a *science of calculation*.
