MATERIALS TOWARD A NATURAL CLASSIFICATION OF THE CYLIN-DRELLOID SNAILS.

BY HENRY A. PILSBRY AND E. G. VANATTA.

While recording some recent additions to the North American landsnail fauna with the intention of revising the "Check List" of United States land mollusks published in these Proceedings for 1889, the attention of the senior author was recalled to the rejection of the generic name Cylindrella by Messrs. Harris and Burrows in 1891, and their substitution of a new name for the group. Upon compiling a list of the generic and subgeneric names which have been applied to species of "Cylindrella," it became obvious that a thorough taxonomic revision was urgently needed. In order to ascertain which of the numerous names should be retained as valid, to place these upon a solid basis, and to reduce the remainder to synonyms, it was found necessary to supplement a review of the literature of the group by an examination of the snails themselves, especially with reference to the radulæ, and the internal characters of the shells, revealed by a study of sections cut to expose the internal columella or axis. This detailed examination has been made chiefly by the junior author of this paper.

The characters of the radula have been utilized as a basis for classification by Crosse and Fischer in 1870, their paper marking an epoch in the taxonomic history of this family. W. G. Binney has added to our knowledge of this subject upon the lines laid down by the French writers; and later, Strebel and Pfeffer, in their suggestive and original series of papers upon the Mexican fauna, have made important contributions toward a rational classification of the group. There are many other writings bearing upon the nomenclature of the Cylindrellas, but no others of importance for original facts or views concerning their phylogeny or structure, aside from mere species work.

The external conchologic characters of the Cylindrellas are well known by the writings of Pfeiffer, Poey and others, but the modifications of the internal armature have been far less fully elucidated. A portion of Pfeiffer's descriptions mention briefly the internal structure, and some of the plates of the Novitates Conchologicæ

and Malakozoologische Blätter represent it; and Arango, in his Contribucion a la Fauna Malacologica Cubana, notes the internal structure of the Cuban species. Most of these observations, however, are not sufficiently detailed or exact to meet the requirements of the case, now that a classification is based largely upon internal structure; and our own work is therefore founded wholly upon the study of a series of sections including nearly every species in the collection of the Academy.

Without entering into any elaborate exposé or criticism of the work of former authors upon the Cylindrellas, attention should be directed to the contention of Crosse & Fischer¹ and later of Fischer² that the series should be distributed between two family groups, the Cylindrellidæ and the Pupidæ, a conclusion based wholly upon the structure of the teeth and jaws; the first family having greatly modified teeth and plaited jaw, the second having normal dentition and solid jaw.

That this splitting of the Cylindrellas into two is an unnatural division, seems to us to be proven by the following considerations: (1) The discovery of completely Cylindrelloid shells (Epirobia) with the "normal" type of teeth. (2) The presence of transition stages in the teeth in the genus Holospira, and (3) the recent demonstration by the senior author of this paper3 of the rapid changes undergone by the teeth of some genera under the stress of changed habits, without corresponding changes in the rest of the anatomy, as seen in Papuina, Polymita, etc. (4) The general law of change in the structure of the jaw, as illustrated in the families Endodontide and Helicide, must now be recognized as largely discounting the old value placed upon that organ as a factor in systematic malacology; and in any family of snails we may expect to find both the more primitive plaited and the later solid type of jaw. final reason for rejecting the idea that any of the group under consideration are Pupidae, is that none of them, so far as known, possess the extremely characteristic complication of the male genital organs found in Pupa, Buliminus, Clausilia, and their immediate allies, and which constitute one of the most important characters of the family Pupidæ.

¹ Journ. de Conchyl., 1870. ² Manuel de Conchyliologie.

³ Manual of Conchology (2), IX, introduction and portions relating to arboreal Helices.

Our further observations upon the family may be grouped under five heads:—

- I. Names applied to generic and minor groups of Cylindrelloid snails.
- II. Key to the genera and subgenera.
- III. Classified lists of the species with zoo-geographic and other notes.
- IV. Brief sketch of other genera of the family.
- V. Provisional phylogenetic diagram and table of geographic distribution.

I. CHRONOLOGICAL LIST OF NAMES APPLIED TO CYLINDRELLOID SNAILS.

(Exclusive of those pertaining to Lia, Macroceramus, Holospira, and other generally recognized genera).

1822 (or earlier). Cochlodina Férussac, Tableau Systematique, etc., p. 24, 61.

Under *Helix*, Férussac establishes a "Quatorzième sous-genre. Cochlodine, *Cochlodina* nobis." The subgeneric definition applies better to *Clausilia* than to the other forms included by Férussac in the group; and, indeed, seems to be based wholly upon that genus.

The species of Cochlodina are classified as follows:—

- *Shell dextral.
- † Aperture without teeth or laminæ.

1. Peristome not continuous.

Premier groupe. Les Pupoides, Pupoides.

- 493 carinata Gmel. [=Macroceramus lineatus Brug.].
- 494 nebulosa nobis. [nomen nudum].
- 495 ignifera nobis, [nomen nudum].

2. Peristome continuous.

Deuxième groupe. Les Tracheloides, Tracheloides.

- 496 sloanii nobis. [nomen nudum].
- 497 draparnaldi nobis. [nomen nudum].
- 498 petiveriana nobis. [probably=C. eximia Pfr.].
- 499 blainvilliana nobis. [nomen nudum].
- 500 cylindrus Chemn. [= Cylindrella].
- 501 rosata nobis. [nomen nudum].
- 502 truncata Dillw. [Undeterminable?=Megalomastoma].
- 503 fasciata Lam. [Undeterminable?=Megalomastoma].

504 tortuosa Chemn. [= Tortulosa tortuosa, an oriental operculate).

505 gracilicollis nobis. [nomen nudum].

506 perplicata nobis. [nomen nudum].

507 collaris nobis. [=Cylindrella].

508 subula nobis. [nomen nudum].

509 antiperversa nobis. [nomen nudum].

†† Aperture armed with large folds or long teeth.

510 gargantua nobis [nomen nudum=Odontostomus].

** Shell sinistral.

1. Aperture without laminæ.

Troisième groupe. Les Anomales, Anomales; Pupa Drap.

511 perversa L. [=Balea].

512 chemnitziana nobis. [Cylindrella elongata Chemn.].

2. Aperture armed (with laminæ or an elastic operculum).

Quatrième groupe. Les Clausilies, Clausilie; genre clausilie Drap.

[Includes the species of Clausilia, with some nomina nuda perhaps pertaining to other groups].

It will be seen that *Cochlodina* is a miscellaneous group, including species of at least six modern genera, all of which have since been named. Under these circumstances it had better be left as a synonym of *Clausilia*, as the diagnosis precludes its use for any of the other groups included.

1828. Brachypus Guilding, Zool. Journal, III, p. 167. Proposed for *B. costatus* Gldg. Preoccupied in *Aves* by Swainson, 1824, and in *Diptera* by Meigen in the same year.

1837. UROCOPTIS Beck, Index Moll., p. 83. Species, petiverana Fér., blainvilliana Fér., cylindrus Ch., Dw. and Wood; rosata Fér., glandula B., abbreviata B., coarctata B., List H., XXI, 17; truncatula Lam. (Clausilia), gracilicollis Fér.

J. E. Gray, in Proc. Zool. Soc. Lond., 1847, p. 177, selects "Turbo" cylindrus as type. This would make the group equivalent to Thaumasia Alb. a later name. Von Martens, in Die Heliceen, 1860, names decollata Nyst as type. This species belongs to Crosse and Fischer's later group Eucalodium; and as it does not appear in Beck's original list of species, must be rejected from the group. Urocoptis is the earliest tenable name for any genus of the family.

1837. Brachypodella Beck, Index Moll., p. 89. Proposed for perplicata Fér., collaris Lam., subula Fér., antiperversa Fér.

1837. Apoma Beck, Index Moll., p. 89. For *elongata* Chemn. (*chemnitziana* Fér.). Gray, 1847, and Mörch, 1852, retain the name for this species.

1840. CYLINDRELLA Pfeiffer, Archiv für Naturg., p. 41. For the following species:

Gracilicollis Fér. [a Brachypodella] collaris Lam. [a Brachypodella] antiperversa Desh. [a Brachypodella], subula Desh. [type of the later group Mychostoma Alb.], perplicata Fér. [a Brachypodella], chemnitziana Desh. [type species of the earlier group Apoma Beck], elegans Pfr. [type of the later group Gongylostoma Alb.], crispula Pfr. [a species of the later group Gongylostoma], ? torticollis (Oliv.) Lam. [= Clausilia of the section Bitorquata Bttg.].

Another Cylindrella, in Conidæ, was proposed in 1840 by Swainson (Malacology, p. 311), and still again, for the group now generally known as Cylichna (t. c. p. 326. See Man. of Conch., XV, p. 287). It is now, so far as we know, impossible to decide whether Pfeiffer's group was published prior to Swainson's or vice versa. Cossmann has proposed to substitute the term Distactria (q. v.) for Cylindrella Pfr. As Cylindrella is later than both Urocoptis and Brachypodella, and the same name was used in the same year for two other groups, we reject it from the nomenclature of this family.

1840. SIPHONOSTOMA Swainson, Treatise on Malacol., pp. 168, 333. For costata Gldg. and fasciata (Encycl. Meth., pl. 461, f. 17). Name preoccupied by Voigt in Vermes, 1836; also used in Rotifera, 1832.

1847. Brachypodisca Agassiz, Nomenclator Zool., Index Universalis, p. 51. An emendation, upon etymological grounds, of Brachypodella Beck.

1850. Thaumasia Albers, Die Heliceen, p. 207. Proposed for decollata Nyst, liebmanni Pfr., gruneri Dkr., cylindrus Chemn., sanguinea Pfr., brevis Pfr., binneyana Pfr.

The two first species belong to Eucalodium, the rest to the Jamaican and Haytien group of large Cylindrellas. Name preoccupied by Perty in Arachnida, 1830. Spartina (q. v.) has been proposed as a substitute, but it is superfluous, as the group is a synonym of Urocoptis Beck, 1837.

1850. Mychostoma Albers, Die Heliceen, p. 207. Proposed for subula Fér., collaris Fér., gracilicollis Pfr., hanleyana Pfr., pallida Guild., seminuda Adams.

In the second edition of Die Heliceen, 1860, p. 37, von Martens selects C. subula as type.

1850. Gongylostoma Albers, Die Hel., p. 208. Proposed for sowerbyana Pfr., humboldtiana Pfr., rosea Pfr., variegata Pfr., elegans Pfr., crispula Pfr., sagraiana Pfr., porrecta Gould, philippiana Pfr.

From this list of species, von Martens selected *elegans* as the type, in Die Heliceen, 1860, p. 38.

1850. Casta Albers, Die Heliceen, p. 208, proposed for *elongata* Ch. and *gracilis* Wood, the former selected as type by von Martens, 1860. This group is absolutely equivalent to *Apoma* Beck, 1837.

1852. STROPHINA Mörch., Catal. Yoldi, p. 35. Proposed for laterradii Grat. only.

1853. Trachelia Pfr., Monogr. Hel. Viv., III, p. 564. Proposed for marmorata Shutt., volubilis Morel., porrecta Gld., gracillima Poey, speluncæ Pfr., subtilis Morel., gouldiana Pfr., rugeli, Shutt., riisei Pfr., cinerea Pfr., morini Morel., philippiana Pfr., scalarina Shutt.

These are mainly slender *Brachypodella* species. Name preoccupied by Scopoli in Aves, 1777, by Serv. in Coleoptera, 1834, and by Westwood in Coleoptera, 1839. It is, therefore, rejected from molluscan nomenclature.

1870. Callonia Crosse & Fischer, Journal de Conch., 1870, p. 18. Based upon one species, Cyl. elliotti Poey.

1880. Epirobia Strebel & Pfeiffer, Beitr. zur Kenntniss der Fauna Mex. Land- und Süsswasser-Conch., Theil IV, pp. 77, 85. Proposed for Cylindrella berendti, polygyra, morini (not of Morelet), apiostoma.

This is a valid genus, well distinguished by the dentition and hollow axis.

1891. DISTÆCTRIA Cossmann in Harris and Burrows, Eoc. and Oligoc. Beds Paris Basin, pp. 100, 114. Proposed as a substitute for Cylindrella Pfr., no reason being given for the change. By reference to the list of species originally assigned to Cylindrella, it will be seen that long before the year 1891, every one was amply provided with generic names, Gongylostoma Alb. and Brachypodella Beck including all of them. The name Distæctria, therefore, falls as a synonym. Being of even date with Spartina Harr. & Burr. (q.v.), it might possibly dispute supremacy with that term as a generic name for "Cylindrella" parisiensis Desh.; but it is obvious that that species (which, in our opinion, is not a Cylindrella nor a member of the same family), does not require both a generic and subgeneric name.

1891. Spartina Harris & Burrows, The Eocene and Oligocene Beds of the Paris Basin, pp. 100, 113 (Sept. 23, 1891). Proposed as a substitute for *Thaumasia* Alb., 1850 (not Perty, 1830-1834).

As Thaumasia is based partly on species of Eucalodium (Crosse & Fischer, 1868), and partly on species of Urocoptis (Beck, 1837), the name Spartina falls as a synonym under these groups, unless, indeed, it be retained for the Paris Basin Eocene species described by Deshayes as "Cylindrella" parisiensis, which is the only species mentioned under Spartina by Harris and Burrows. See under Distactria.

II. ANALYTICAL KEY TO CYLINDRELLOID GENERA AND THEIR SUBDIVISIONS.

(Exclusive of the generally recognized genera Lia, Macroceramus, Eucalodium, etc.).

- I. Axis of the shell a solid, not perforated, column; teeth of the radula very peculiar, the centrals very narrow, laterals with gouge-shaped cusps.
 - a. Radula with large posterior cusps (ectocones) upon all of the side teeth, which are of similar form, gradually becoming smaller from the inner to the outer edge of radula, generally with no abrupt break in size between lateral and marginal teeth; rows slanting, "en chevron" (Pl. XVII, fig. 5).

 Genus UROCOPTIS Beck.
 - b. Axis slender and simple, without spiral laminæ or other processes.

 Subgenus Urocoptis.
 - c. Shell large, stout and fusiform; axis straight.

Section Urocoptis s. s.

c1. Shell small, thin and fusiform; axis straight.

Section Cochlodinella P. & V.

c². Shell small, pillar-shaped; axis sigmoid below.

Section Spirostemma P. & V.

- b¹. Axis with a single, strong, smooth spiral lamina, median in each whorl. Subgenus Arangia P. & V.
- b². Axis with two series of hooks curving toward each other, or with a series of oblique nodes or ribs.

Subgenus Idiostemma P. & V.

- b³. Axis with a single stout spiral fold crenulated at the edge. Section *Maceo* P. & V.
- b4. Axis with one or several spiral laminæ, the lower of

which is cut into teeth or crenulated, at least in the earlier whorls. Subgenus Gongylostoma Alb.

- c. Three to seven spiral laminæ developed, increasing in size from the upper to the lowest one, which is largest. Section Pycnoptychia P. & V.
- c¹. Three lamine, the lowest smallest, upper largest. Section Callonia C. & F.
- c². Two subequal spirals; a median whorl with accessory laminæ upon the upper and basal walls.

 Section Sectilumen P. & V.
- c³. Two spirals, the lower dentate in upper whorls, and in an intermediate whorl expanding into a very broad, flat or cup-like plate.

Section Esochara P. & V.

c⁴. Two gradually increasing spirals, the lower crenulate or denticulate; sometimes a short, low, third spiral interposed in an intermediate whorl.

Section Gongylostoma s. str.

c⁵. Two strong, subequal spirals, both crenulated or denticulate (Haiti).

Section Amphicosmia P. & V.

c⁶. One incised or denticulate lower lamina with sometimes a smaller one above it.

Section Tomelasmus P. & V.

a¹. Radula with the posterior cusp (ectocone) sub-obsolete or wanting on the first or both lateral teeth; two laterals on each side enormously developed, the marginals abruptly smaller, narrow, probably functionless, with vestigial cusps; arranged in horizontal lines (Pl. XVII fig. 4). Axis of the shell without laminæ.

Genus BRACHYPODELLA Beck.

b. Inner lateral tooth with a vestigial posterior cusp (ecto-cone) without cutting point; outer lateral with cutting point developed on the ectocone.

Subgenus Brachypodella.

c. Axis slender throughout, rarely with a small spiral fold; shell slender and elongate.

Section Brachypodella s. str.

c1. Axis strong, heavily calloused; shell obese.

Section Strophina Mörch.

- b¹. Inner lateral tooth with no ectocone; that of the outer lateral without cutting point. Species all Jamaican.
 - c. Axis slender, straight; last whorl of shell becoming free, and keeled below; aperture subcircular, angular below, as wide as high.

d. Shell small, narrowly fusiform, with strongly ribbed whorls. Section Geoscala P. & V.

d¹. Shell slender, pillar-like, white and smooth, of many narrow whorls.

Section Mychostoma Alb.

- c¹. Axis a mere edge of contact between whorls; shell white, sinistral, slender, of many oblique whorls, the last not free; aperture oval, longer than wide.

 Section Apoma Beck.
- II. Axis of the shell a hollow column; radula of normal form and arrangement; central teeth tricuspid, short and wide; laterals numerous, similar, bicuspid; marginals wide, very short, multicuspid (Pl. XVII, fig. 2).
 - a. Shell very slender and elongate, thin, not conspicuously calcareous, the axis subcylindrical or bulging in each whorl, usually rugose. Genus EPIROBIA S. & P.
 - a¹. Shell stout, pupiform, with entire spire, conspicuously calcareous, etc., etc. Genus HOLOSPIRA Mart.

III. CLASSIFIED LISTS OF SPECIES.

As the groups defined by us in the preceding table of classification differ radically in limits from those hitherto accepted, it is necessary to supplement the characterization of the genera and subgenera by detailed lists of species. These lists contain only species whose characters we have ascertained by the examination of sections. Those we have not been able to examine are omitted, although a large part of them could doubtless be approximately grouped by the published information.

The names of species of which the radula is known are distinguished by the following symbols: "(CF)" after the name of a species indicates that the dentition has been examined by Crosse &

⁴ The lists are, therefore, a catalogue of the species in the collection of the Academy, excluding a considerable number of doubtful, unidentified or new species. Any forms not mentioned herein we will be glad to receive and offer an exchange for.

Fischer; "(B.)" that it has been examined by W. G. Binney; 6 "(S P.)" by Strebel & Pfeffer; "(P V.)" by ourselves.

Genus UROCOPTIS Beck.

This genus is restricted to Cuba, Jamaica and Haiti, with a few stragglers from the Cuban fauna in south Florida. It is practically a group of the Greater Antilles. The typical forms, with the axis simple, are the most widely spread and probably the oldest type. The large, stout forms being a local development common to Jamaica and Haiti.

The forms with spiral folds or other ornamentation of the axis are confined to Cuba and the adjacent portion of Haiti. There is every reason to believe them autochthonous to Cuban soil, a few species recently spreading eastward.

This genus shows the bond between Jamaica and Haiti to be rather stronger than between Cuba and Haiti, the Cuban groups occurring in Haiti being represented by very few species, and these restricted to the extreme western end of the island.

The elements common to Jamaica and Cuba are the more generalized and presumably older sectional groups of the genus.

Respecting the habits and environment of the Jamaican Cylindrellas of both the genera Urocoptis and Brachypodella, Mr. Charles T. Simpson writes of the experiences of Mr. J. B. Henderson and himself, as follows: "C. sanguinea, rosea, obesa, cylindrus, aspera, brevis and allied forms live on the ground among the scrub and dead leaves, and are of just about the color of their surroundings. We found C. nobilior abundant in a talus of decomposed shaly rock at Bogwalk, of which it was almost exactly the color. C. seminuda, alba and robertsi are found in the crevices of craggy limestone rocks, among cliffs. C. rubra and tenella live in the ground in thickets where there is abundance of dead and decaying wood. The shells, in form and color, always look exactly like pieces of broken twigs, which are found abundantly with them, and it was a long time before Henderson and I found a single specimen. They are very abundant though in proper localities. C. gracilis Wood grows invariably on the trunks and stems of trees in thick scrub. These trees have gravish or whitish spotted bark; the little rascals attach themselves to it by the foot and stand out with the shell nearly at

⁷ Beitr. Mex. Moll.

Journal de Conchyliologie, 1870.
 Ann. N. Y. Acad. Sci., III.

right angles to the trunk or limb, and as the shell is always more or less dirty, the resemblance to a thorn is so astonishing that we doubtless passed by thousands of them, never dreaming for a moment that they were Cylindrellas."

Mr. Uselma C. Smith found B. elongata living on limestone cliffs, upon which the white shells hung like stalactites, for which he at first mistook them.

Subgenus Urocoptis Beck.

Type *U. cylindrus* (Chemn.), Pl. XVIII, fig. 11 (axis) and Pl. XVII, fig. 5 (dentition).

Section UROCOPTIS, s. s.

Species of Jamaica.

U. amethystina (Chitty).	U. megacheila (Chitty).
U. aspera (Ad.).	U. nobilior (Ad.).
U. baquieana (Chitty).	U. procera (Ad.).
U. brevis (Pfr.) [C F.].	U. rosea (C. B. Ad. not Pfr.)
U. carnea (Ad.).	[C F., B., S P., P V.].
U. cylindrus (Chemn.).	U. sanguinea (Pfr.) [C F.].
U. gravesii (Ad.).	U. zonata (Ad.).
U. lata (Ad.).	

Species of Hayti.

U. adamsiana (Pfr.).	U. gruneri (Pfr.).
U. arcuata (W. & M.).	U. gruneri (Pfr.). U. guigouana (Petit).
U. crenata (W. & M.).	U. mabuja (Weinl.).
U. eugenii (Dohrn).	U. malleata (Pfr.).
U. eximia (Pfr.).	U. menkeana (Pfr.).
U. flammulata (Pfr.).	U. puncturata (Pfr.).

Section Cochlodinella Pils. & Van.

Type *U. poeyana* (Orb.). Radula with 12.1.12 teeth, which are typical for the genus in form, but decrease rather rapidly.

Species of Cuba and Florida.

U. angulifera (Gundl.).	U. mamillata (Wright).
U. atropurpurea (Arango).	U. mixta (Wright).
U. goniostoma (Gundl.).	U. paradoxa (Arango). U. poeyana (Orb.) [B., P V.]. U. presasiana (Pfr.).
U. illamellata (Wright).	<i>U. poeyana</i> (Orb.) [B., P V.].
U. jejuna (Gld.).	U. presasiana (Pfr.).
U. lactaria (Gld.).	U. variegata (Pfr.).

Species of Jamaica.

U. augustæ (C. B. Ad.). U. hollandi (C. B. Ad.).

U. pupæformis (C. B. Ad.). U. striata (Chitty).

U. hydrophana (Chitty).

Section Spirostemma Pils. & Van.

Type U. rubra (C. B. Ad.), Pl. XVIII, fig. 12. The species are all Jamaican.

U. dunkeriana (Pfr.).

U. montana (C. B. Ad.).

U. princeps (C. B. Ad.).

U. similis (C. B. Ad.).
U. tenella (C. B. Ad.).
U. tenera (C. B. Ad.).

U. pusilla (C. B. Ad.).

Subgenus Arangia Pils. & Van.

Type C. sowerbiana Pfr., Pl. XVIII, fig. 20. Subgeneric name in memory of the Cuban naturalist, Rafeal Arango.

U. sowerbiana Pfr., Cuba.

U. monticola Weinl. Gonave I.

Subgenus Idiostemma Pils. & Van.

Type C. uncata Gundl., Pl. XVII, fig. 10.

A Cuban group, containing some of the most peculiar species of the genus. There is a series of species leading by gradual stages from the axial pairs of hooks of the typical forms to the oblique nodes or ribs of U. lateralis, etc.

U. uncata (Gundl.).
U. perlata (Gundl.) [C F., P.V.]
U. fastigata (Gundl.).
U. lævigata (Gundl.).
U. lineata (Gundl.).
U. lateralis (Paz.) [P V.].

Section Maceo Pils. & Van.

Radula with the teeth very rapidly decreasing, the third decidedly smaller than second, formula about 8.1.8. Subgeneric name in honor of a Cuban patriot.

U. interrupta (Gundl.) [P V.], Cuba. Pl. XVII, fig. 7.

Subgenus Gongylostoma Albers.

Section Pycnoptychia Pils. & Van.

Type U. humboldtiana (Pfr.), Pl. XVIII, fig. 14. Species all Cuban.

U. humboldtiana (Pfr.) [B.].

U. striatella (Wright).

U. oviediana (D. Orb.).

U. trilamellata (Pfr.).

U. scæva (Gundl.) [C F.].

U. vignalensis (Wright) [CF].

U. shuttleworthiana (Poey).

Section Callonia Crosse & Fischer.

Type C. elliottii Poey. Radula typical. See Pl. XVIII, fig. 18, U. dautzenbergiana (Crosse). Species all Cuban.

We have enlarged the group of Crosse and Fischer to include other Cuban species having the same internal structure and dentition.

Species elaborately sculptured with hollow ribs:—

U. elliottii (Poey) [C F.].

U. dautzenbergiana (Crosse)

Somewhat smooth species:—

U. brunnescens (Gundl.).

U. clara (Wright).

U. guirensis (Gundl.).

U. infortunata (Arango).

U. vincta (Gundl.). U. saxosa (Poey).

Species with beaded suture:—

U. albocrenata (Gundl.)

Section Sectilumen Pils. & Van.

U. ornata (Gundl.) [B., P V.]. Cuba. Pl. XVII, fig. 9.

Section ESOCHARA Pils. & Van.

Type U. strangulata (Poey), Pl. XVIII, fig. 15. Distribution, Cuba.

U. fabreana (Poey) [P V.].

U. teneriensis (Wright).

U. strangulata (Poey).

Section GONGYLOSTOMA Albers (restricted).

Type U. elegans (Pfr.), Pl. XVIII, fig. 17 (variety). Also Pl. XVIII, fig. 16, U. pruinosa. Distribution, Cuba.

U. artemesiæ (Gundl.).

U. auberiana (D. Orb.).

U. concreta (Gundl.).

U. coronadoi (Arang).

U. crispula (Pfr.).

U. elegans (Pfr.) [B., P V.].

U. fortis (Gundl.).

U. gutierezi (Arango).

U. lavalleana (Orb.). U. obliqua (Pfr.).

U. planospira (Pfr.).

U. pruinosa (Morel.) [P V.].

Section Tomelasmus Pils. & Van.

Type U. torquata (Morel.), Pl. XVII, fig. 8; also Pl. XVIII, fig. 13, U. wrighti var. Radula typical. Species all Cuban.

U. aculeus (Morel.). U. heynemani (Pfr.). U. acus (Pfr.). U. hidalgoi (Arango). U. adnata (Pfr.). U. hilleri (Pfr.) [P V.]. U. affinis (Pfr.) [P V.]. U. incerta (Arango). U. angustior (Wright). U. integra (Pfr.). U. arcustriata (Wr.). U. irrorata (Gundl.). U. assimilis (Arango). U. macra (Wright). U. capillacea (Pfr.). U. plumbea (Wright). U. coerulans (Poey). U. producta (Gundl.). U. sauvalleana (Gundl.) [PV.]. U. colorata (Arango). U. crenulata (Gdl.). U. scabrosa (Gundl.). U. crystallina (Wright). U. thomsoni (Arango). U. decolorata (Gundl.). U. torquata (Morel.). U. diaphana (Wright). U. unquiculata (Arango). . U. discors (Poey). U. ventricosa (Gundl.) [P V.] U. fibrosa (Gundl.). U. violacea (Wright). U. jusiformis (Wr.). U. wrighti (Pfr.). U. garciana (Wright).

Section AMPHICOSMIA Pils. & Van.

Type C. salleana Pfr., Pl. XVIII, fig. 22.

Proposed for three San Domingo species in which the columella bears two spiral laminæ, both finely denticulate.

U. salleana (Pfr.).

U. gracilicollis (Auct.).

U. hjalmarsoni (Pfr.).

Genus BRACHYPODELLA Beck, 1838.

In this genus the radula is more highly specialized than in Urocoptis and the shell generally less so, internal armature of the axis being entirely absent, or limited to a weak, scarcely noticeable, spiral fold above.

The geographic range of Brachypodella includes not only the territory occupied by Urocoptis, but surpasses it on all sides: in the Bahamas on the north, the Virgin group on the east, the whole Caribbean chain and northern border of South America on the south, and west and southwest is sparsely distributed over Central America and southeastern Mexico.

The distribution of the minor groups is suggestive. The Jamaican sections form a group by themselves characterized by the extremely aberrant dentition as well as the modified shells. cies of other islands and the mainland are decidedly less specialized,

and show but a small amount of variation in general appearance. The section Strophina has the dentition of typical Brachypodella.

Section BRACHYPODELLA 8. 8.

Type B. antiperversa Fér.

This subgenus has a less specialized radula and wider geographic range than the others. The species are all small, mainly quite slender forms, for the most part not exhibiting great variety of form; but two exceptions may be noticed: B. brooksiana of Cuba, and some related species, have the neck enormously drawn out; while in some of the continental forms there is a weak spiral lamina upon the pillar.

Continental Species: Tabasco and Yucatan to Venezuela.

B. bourguignatiana (Ancey).

B. hanleyana (Pfr.).

B. morini (Morel.).

B. speluncæ (Morel.).

B. speluncæ var. dubia (Pils.).
B. subtilis (Morel.).

Insular species: Curacao and Trinidad to Porto Rico.

B. raveni (Bld.). Curacao.

B. trinitaria (Pfr.) [P V.]. Trinidad.

B. costata (Gldg.) [C F.]. Bar-

B. antiperversa (Fér.) [P V.]. Guadeloupe.

B. collaris (Auct.) [PV.]. Guadeloupe, Martinique.

B. pallida (Gldg.). St. John, Tortola, St. Thomas, Porto Rico.

B. chordata (Pfr.). St. Croix.

B. portoricensis (Pfr.). Rico.

B. riisei (Pfr.) [P V.]. Rico.

Greater Antilles—Haiti.

B. dominicensis (Pfr.).

B. gouldiana (Pfr.).

B. obesa (Weinl. & Mts.).

B. smithiana (Pfr.).

B. weinlandi (Pfr.).

Greater Antilles—Cuba.

B. blainiana (Gundl.).

B. brooksiana (Gdl.) [C F., P. V.].

B. camoensis (Pfr.).

B. capillacea (Pfr.).

B. cyclostoma (Pfr.) [B., P V.].

B. modesta (Poey).

B. philippiana (Pfr.).

B. plicata (Poey) [P V.].

B. porrecta (Gld.).

B. rugeli (Shutt.).

B. scalarina (Shutt.).

B. gracillima (Poey).
B. gundlachiana (Poey).
B. marmorata (Shutt.).
B. minuta (Gundl.).
B. turcasiana (Gundl.).

Bahamas.

- B. bahamensis (Pfr.). New Providence, [C F., P V.]. Section Strophina Mörch.
- B. laterradii (Grat.) [P V.]. San Domingo.

Section Geoscala Pils. & Van.

Type B. seminuda (C. B. Ads.).

A Jamaican group similar to some Brachypodellas except in the dentition, which is of the highly evolved type seen in *Mychostoma*. The shell differs from this last group in being fusiform, fewer whorled and strongly costate.

Subgenus Mychostoma Albers.

Mychostoma Alb., Die Hel. (edit. 1), p. 207. All species are Jamaican.

B. agnesiana (C. B. Ad.) [C F., B. alabastrina (Pfr.).
P V.].
B. alba (Ad.).
B. subula (Fér.) [B.].

Subgenus Apoma Beck.

Apoma Beck, Index Moll., p. 89.

Casta Alb., Die Hel., p. 208.

A very distinct group, containing two sinistral Jamaican species. Type Turbo elongatus (Wood), Pl. XVIII, fig. 21.

Von Martens objects to the name Apoma because of its inapplicability as implying that other allied groups should be operculated; but it was obviously given to direct attention to the most conspicuous difference between this group and Clausilia, and from this point of view is eminently appropriate.

B. gracilis (Wood) [C F., S P.]. | B. elongata (Chemn.) [B., P V.].

Genus ANOMA Albers.

1850. Anoma Alb., Die Heliceen, p. 209, for acus Pfr., gossei Pfr., tricolor Pfr. (the last selected as type by von Martens, Die Hel. 2d edit., 1860, p. 269). Not Anomus Fairm. Hemiptera 1846.

1850. Leia Albers, Die Hel., p. 207. Sole species L. maugeri Wood. Not Leia Meigen in Diptera, 1818, nor Meg., Coleoptera, 1821.

1852. Lia Mörch, Catal. Yoldi, p. 35. Sole species L. maugeri. Not Lia Esch., in Coleoptera, 1829.

1869. Inliaculus Schaufuss, in Paetel's Moll. Syst. et Catal., p. 15.

1894. Vendrysia Simpson, Proc. U. S. Nat. Mus., xvii, p. 430. Substitute for Leia.

Distribution, Jamaica; mountains of the interior.

Of the several names proposed for this group, Anoma has priority. It has the disadvantage of being preceded by Anomus, which some writers would hold to be identical. Those adhering to this view will adopt the name Inliaculus of Schaufuss; but pending some concerted action upon this point in "nymology" the oldest name may be allowed to stand.

The dentition (Pl. XVII, figs. 3 and 6, A. maugeri) is extremely peculiar, differing from that of *Urocoptis* in having the cusps of the teeth serrate.

A. maugeri. (Wood).
A. blandiana (Pfr.).
A. macrostoma (Pfr.).
A. gossei (Pfr.).

Genus MACROCERAMUS Guilding.

1822. Cochlodina, 1re groupe, Pupoides Fér., Tabl. Systematique, p. 24, 61.

1828. Macroceramus Guilding, Zool. Journ., IV, p. 168. M. signatus.

1850. Colobus Alb., Die Heliceen p. 177. Not of Illiger, 1811, Merrian, 1820 (Rept.), or Serv., 1833 (Coleopt.).

For anatomy see Crosse & Fischer, Journ. de Conchyl., 1870, p. 20; Moll. Terr. Mex., I, p. 419. Binney, Terr. Moll., V, p. 384; Ann. N. Y. Acad., III, p. 126. Strebel & Pfeffer, Beitr. Mex. L. u. S.-W. Conch., IV, p. 89.

Preponderantly Antillean, this genus has representatives upon the mainland bordering the Gulf of Mexico from Venezuela to Florida. These peripheral species are apparently all members of the section *Microceramus*. In the West Indies the genus is present on nearly every island, but is especially developed in Cuba, to which *Spiroceramus* is confined. It is poorly represented in Jamaica by a few species of the group *Microceramus*, to which the species of the Bahamas likewise belong.

Synopsis of subgenera.

I. Axis slender, straight and simple.

a. Macroceramus. Shell comparatively solid and large. Type M. signatus Gldg.

a'. Microceramus Pils. & Van., (n. s.-g.). Shell smaller, thin. Type M. floridanus Pils.

II. Axis with a strong spiral lamina.

Spiroceramus Pils. & Van., (n. s.-g.). Dentition unknown. Type M. amplus Gundl.

Genus PINERIA Poey.

This small group, originally described from the Isle of Pines, but also occurring in several of the Caribbean Islands, is probably an offshoot of the genus *Macroceramus*. The peculiar features of the external anatomy described by Poey should be re-examined.

Genus EPIROBIA Strebel & Pfeffer, 1880.

Epirobia S. & P., Beitrag zur Kenntniss der Fauna mexikanischer Land- u. Süsswasser-Conchylien, Theil IV, pp. 77, 85.

Type E. polygyra Pfr. Pl. XVII, fig. 2 (dentition). For figure of the axis, see Strebel, l. c., pl. 14, f. 14.

Many-whorled, slender species of Eastern Mexico, usually retaining the spire intact, differing from *Urocoptis* and *Brachypodella* in dentition and in the hollow axis. Notwithstanding the entirely "Cylindrella"-like aspect of the shell externally, these features unquestionably locate the group near *Holospira* and *Cælocentrum*.

Strebel and Pfeffer referred all of the Mexican Cylindrellas to their group; but it must be restricted by removal of the forms with solid axis, which apparently belong to Brachypodella. In addition to the two species mentioned below, E. berendti Pfr. [S P.] belongs here, and probably gassiesi Pfr. and swiftiana Crosse also. The "E. morini Morelet," of Strebel & Pfeffer was incorrectly identified, and probably a form of E. polygyra. The true C. morini is a Brachypodella with acutely keeled base.

E. polygyra Pfr. [S P., P V.].

E. apiostoma Pfr.

⁸ Since this paper was written, this form has been referred by Dr. von Martens to C. polygyrella Mts. It is a true Epirobia.

Genus HOLOSPIRA von Martens.

This genus, which is confined to the mainland of Mexico and the adjacent States of the Union, offers an interesting series of structures in the internal lamelle, parallel to those of *Urocoptis*. The principal divergence from that genus is in the frequent development of parietal and basal lamellæ, which are of rare occurrence in the Antillean genera.

Professor Dall, who has ably investigated the subject, gives the following classification, which seems worthy of unqualified approval:-

Subgenus Holospira s. s., type N. pilocerei Pfr., with section Bostrichocentrum Strebel & Pfeffer, Haplostemma, Eudistemma and Distomospira Dall.

Subgenus Metastoma Strebel & Pfeffer, type H. roemeri Pfr. Subgenus Cœlostemma Dall, type H. elizabethæ Pilsbry.

The first group includes species with an axial plait and usually More or less similar structures occur in various other armature. Gongylostoma. Metastoma has the axis simple, as in typical Urocoptis and Brachypodella. In Coelostemma a swollen, vertically costulate axis is found, unlike any Antillean type, although there is some analogy with the subgenus Idiostemma Pils. & Van.

Genus EUCALODIUM Crosse & Fischer.

In this Mexican genus the large, solid shell resembles typical Urocoptis; the axis is solid and sinuous, with a continuous spiral plait, as in the subgenus Arangia P. & V., of Urocoptis.

The subgenus Oligostylus Pils. 10 has the axis straight and smooth, as in typical Urocoptis.

These two types of pillar are exactly paralleled also in the genus Macroceramus Gldg. and its subgenus Spiroceramus Pils. & Van.

Subgenus Anisospira Strebel & Pfeffer.

An eastern Mexican group, of few species. The soft anatomy is It seems to be a subgenus subordinate to Eucalostill unknown. dium.

Genus BERENDTIA Crosse & Fischer.

Like Spartocentrum, to which it is closely allied; but with the axis solid, slender and smooth, and the spire tapering, with fewer, more

Proc. U. S. National Museum, xix, p. 344, 1896.
 See Dall, The Nautilus IX, p. 51; Proc. U. S. Nat. Mus. XIX, p. 348.

rapidly widening whorls. The only species, B. taylori Pfr., inhabits the table land of Lower California.

Genus CŒLOCENTRUM Crosse & Fischer.

The hollow and usually vertically ribbed axis is unlike any of the Antillean types, although radiating spines, such as Dall describes in C. astrophorea, recall certain forms of Gongylostoma. In the section Spartocentrum Dall¹¹ there is a spiral inflation and no vertical riblets.

Genus CERION (Bolt.) Mörch.

See Proc. Acad. Nat. Sci. Phila., 1896, p. 315.

This genus has generally been placed in the neighborhood of Pupa, but it is not closely allied to that group in shell characters and is entirely diverse in genitalia. It may possibly belong to the Odontostominæ (Odontostomus, Tomigerus, Anastoma) of South America; but we prefer to associate Cerion with the Holospira and Eucalodium groups of Urocoptidæ.¹²

As this genus has been made the subject of special papers by Dr. W. H. Dall and by the present writers, it need only be said here that it differs from the other genera in being strictly littoral in distribution, never straying far from the sea shore. The Miocene forms (Eostrophia) are probably aberrant rather than primitive, in lacking parietal and axial laminæ.

Genus MEGASPIRA Lea.

A Brazilian group very peculiar in its polygyrate shell with large, rounded nuclear whorls, plicate columella and peculiar internal armature, somewhat recalling *Gongylostoma*, *Idiostemma*, etc. This has been described and figured by Gabb.¹³ The dentition we have now examined (Pl. XVII, fig. 1), the radula having been found in a dry shell. There are 28·1·28 teeth, arranged in slightly sinuous transverse rows, and of the type usual in ground snails, much like those of *Eucalodium*, *Berendtia*, etc.

character, viz., the hollow axis.

12 Dall has hinted at the same relationship. See Proc. U. S. Nat. Mus., XIX, p. 347, 348, 1897.

¹³ American Journal of Conchology II, p. 64.

¹¹ See Nautilus IX, p. 51 (Sept., 1895), type Cælocentrum irregulare Gabb. The genus Teneritia Mabille, Bull. Soc. Philomathique de Paris, (Ser. 8), Vol. IX, p. 79 (1897 or 1898) is a synonym of Spartocentrum. Types Berendtia digueti and B. minorina Mabille. M. Mabille is perfectly right in separating his group from Berendtia, but he overlooks the only really important differential character, viz., the hollow axis.

Megaspira was placed in the vicinity of Clausilia by Deshayes, who thought the internal structure indicated the presence of a clausilium. This inference does not seem justified by the facts of the case, though we are far from denying its possibility; our specimen with the soft parts dried in shows no trace of a clausilium. Upon the whole, it would appear that Megaspira is an aberrant member of the Urocoptidæ, nearest perhaps to Eucalodium among existing genera.

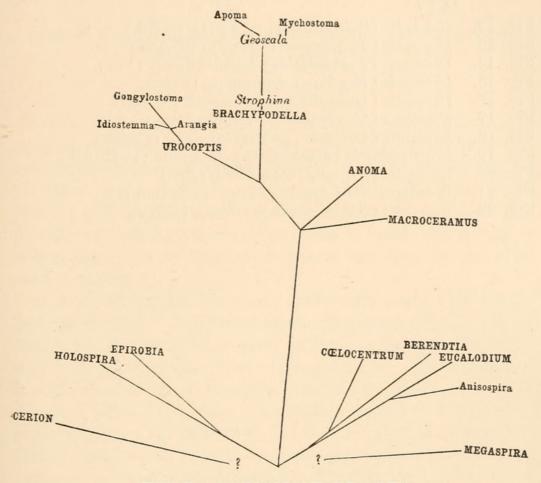

The South African genus Cælaxis and the Papuan and Australian Perrieria are somewhat similar to the foregoing American genera, but are doubtless correctly referred to Pupidæ, near Clausilia. Perrieria has a complicated internal armature, only partially worked out by Fischer.

The Colombian *Rhodea* is probably referable to the *Achatinidæ*, grouping near *Subulina* Beck (type *S. octona*).
